

Firewall

How is it possible for a stateful firewall to allow an external packet to access the internal resources of a network?

Selecione uma alternativa

- A** It's possible if this packet is a response from a request originated on the inside network (trusted zone).
- B** This is not possible in any circumstance.
- C** The only way this can happen is to configure an exception on the firewall to let this packet get inside the network, otherwise a traffic initiated from an outside network will never be allowed to get inside.
- D** By default a stateful firewall will allow every packet from outside to be forwarded to the inside network, it happens because every traffic is initially trusted and will only be blocked if an anomaly is detected
